

# The Permutations Paper for non Algebraic Speakers.

David Ponarovsky

May 21, 2023

## Abstract

A guide for reading Becker, Lubotzky, and Mosheiff's paper for computer scientists. The goal is to help the reader by providing analogs and examples from the combinatorics field.

## 1 Motivation (Use Cases List).

We start by presenting several use cases that may be of interest to computer scientists.

1. Testing candidates for LTC/QLDPC codes. One of the resources needed for the available constructions is a square complex in which the encoding associates each bit with a face. We can obtain these structures by taking the Left-Right Cayley graph generated by a pair of generator sets  $A, B$ , such that  $[A, B] = 0$ .
2. Testing if a set of stabilizers forms a stabilizer code. Here the stabilizers are subsets of the Pauli group and they form a code only if they all commute.
3. Classical toy-version of QMA complete problem. It's known that decide if two quantum circuits over  $n$  qubits are  $1/poly$ -equivalent is QMA-complete problem. So, One question that could be interesting is to ask given prem'  $P = \prod p_i$  and  $Q = \prod q_i$  such that  $p_i$  ( $q_i$ ) act over a constant size of bits (assuming binary encoding), then ask whether  $P = Q$ .

We think about the testability of hardness as a property of the equations, not the permutations. To motivate this, we can consider the implementation of memory, with the motion of each particle governed by the configuration of the system, which are our encoded codewords.

One illustrate is the commuting equation, in which we ask to decide if two given permutations  $X, Y$  are commute or not. It's know that this relation is stable, meaning that if they almost commute then they are close to groups which are completely commute. An example for relation which is not stable is  $Y^2X = XY^2$ . In general it is an open question whether exist  $m \neq n$  such that  $Y^mX = XY^n$ .

**Fact 1.** *Locally testable preserved under isomorphism over **finite** groups.*

- $\Rightarrow$  Abelian group are locally testable.
- 

## 2 Example.

Let us define the permutations  $f, g$  over  $n = 2m$  elements defined as follow:

$$f(i) = \begin{cases} i+1 & i < m \\ i-1 & i \geq m \end{cases}$$

reflection

$$g(i) = \underbrace{n-i}_{\text{reflection}} + 1$$

## 3 The $S$ -graph.

**Theorem 1.** *Denote by  $FGSol_E$  union over the finite connected entities of  $GSol$ , and by  $\alpha$  the asymptotic (ifimum) Cheeger constant of them. If the  $\alpha$  is positive, then  $E$  is not testable.*

## 4 Not Locally Testable.

Abels's group is solvable, residually finite, but not locally testable.

$$G = \text{diag}(1, p^m, p^n, 1) + \text{upper}$$

## 5 Defs.

**Definition 1.** *The uniform local defect of  $f : \Gamma \rightarrow \text{Sym}(n)$  is*

$$\text{def}_\infty(f) = \sup_{\gamma_1, \gamma_2 \in \Gamma} \{d^H(f(\gamma_1\gamma_2)), f(\gamma_1)f(\gamma_2)\}$$

*The uniform distance between  $f, g : \Gamma \rightarrow \text{Sym}(n)$  is*

$$d_\infty(f, h) = \sup_{\gamma \in \Gamma} \{d^H(f(\gamma), h(\gamma))\}$$

**Definition 2.** *For  $\sigma, \tau \in \text{Sym}(n), \text{Sym}(N), n \leq N$*

$$d^H(\sigma, \tau) = d^H(\tau, \sigma) \\ = \frac{1}{N} (|\{x \in [n] | \sigma(x) \neq \tau(x)\}| + N - n)$$

*$d^H$  is a metric on  $\bigcup_{n \in \mathbb{N}} \text{Sym}(n)$  and the idea is to punish permutations that use much more space then  $\sigma$ .*

## 6 Facts.

**Fact 2.** *Amenable + Locally testable  $\Rightarrow$  Every finitely generated normal subgroup is closed.*

**Fact 3.** *The discrete Heisenberg group  $H_3(\mathbb{Z}) = \langle x, y, z | [x, z] = [y, z] = 1, [x, y] = z \rangle$  is locally testable.*

**Fact 4.** *the Bamuslag-Solitar  $BS(1, 2) = \langle x, y | yx = x^2y \rangle$  is locally testable.*

**Fact 5.** *Infinite + Sofic + Property(T)  $\Rightarrow$  not locally testable.*

**Fact 6.** (Kazhdan 82) *Let  $H$  be an Hilbert space and  $f : \Gamma \rightarrow U(H)$  such that:*

$$\sup_{\gamma_1, \gamma_2 \in \Gamma} |f(\gamma_1\gamma_2) - f(\gamma_1)f(\gamma_2)|_{op} \leq \delta$$

*then there is representation  $h : \Gamma \rightarrow U(H)$  such that  $\sup_{\gamma \in \Gamma} |h(\gamma) - f(\gamma)|_{op} \leq 2\delta$  In other words, any function which approximate a distance between groups elements is close to homomorphism.*

**Fact 7.** *If  $\Gamma$  is finite and  $f : \Gamma \rightarrow \text{Sym}(n)$  then there is a homomorphism  $h : \Gamma \rightarrow \text{Sym}(n)$  such that:*

$$d_\infty(h, f) \leq C \text{def}_\infty(f)$$

*where  $C$  depends only on  $\Gamma$  (and not on  $n$ )*

**Definition 3.** *If  $\Gamma$  acts transitively on  $[n]$  then there is  $f : \text{Sym}(n-1)$  such that:*

$$\text{def}_\infty(f) \leq \frac{2}{n-1}$$

*but*

$$d_\infty(h, f) \geq \frac{1}{2} - \frac{1}{n-1}$$

*for every homomorphism  $h \rightarrow \text{Sym}(n-1)$*

**Fact 8.** If  $\Gamma$  is amenable  $f : \Gamma \rightarrow U(n), \delta > 0$  and

$$|f(\gamma_1\gamma_2) - f(\gamma_1)f(\gamma_2)|_h \leq \delta \quad \forall \gamma_1\gamma_2 \in \Gamma$$

then there is a representation  $h : \Gamma \rightarrow U(N)$  and an isometry  $T : \mathbb{C}^n \rightarrow U(N)$  such that:

$$|h(\gamma) - T^\dagger f(\gamma) T|_h \leq 211\delta \quad \forall \gamma \in \Gamma$$

and  $n \leq N \leq (1 + 2500\delta^2)n$ . Here  $|A|_h = \left(\frac{1}{n}\text{tr}(A^\dagger A)\right)^{\frac{1}{2}}$

**Fact 9.** For amenable  $\Gamma$  and function  $f : \Gamma \rightarrow \text{Sym}(N)$  such that:

$$d_\infty(h, f) \leq \varepsilon \quad \text{and } n \leq (1 + \varepsilon)n$$

where  $\varepsilon \leq 2039 \cdot \text{def}_\infty(f)$

**Fact 10.** Let  $f : SL_r(\mathbb{Z}) \rightarrow \text{Sym}(n), r \geq 3$ . Then there is a homomorphism  $h : SL_r(\mathbb{Z}) \rightarrow \text{Sym}(N)$  such that:

$$d_\infty(h, f) \leq C \text{def}_\infty(f) \\ \text{and } n \leq N \leq (1 + C \text{def}_\infty(f))n$$

## 7 Randomized Banchmark.

**Definition 4** (unitary  $t$ -design.). A set of unitary operations on  $\mathbb{C}^D$  such that, for every polynomial  $P_{(t,t)}(U)$  of degree at most  $t$  in the matrix elements of  $U$  and at most  $t$  in the complex conjugates of those matrix elements we have:

$$\frac{1}{K} \sum_{k=1}^K P_{(t,t)}(U_k) = \int_{U(D)} dU P_{(t,t)}(U)$$

where the integral is respect to the unitarily invariant Haar measure. Example for  $P_{(1,0)} : U, P_{(2,2)} : U_k U_j U_k^\dagger U_j$

**Definition 5.** The super operator  $\mathbb{E}_\mu(\Lambda)$  define to be:

$$\mathbb{E}_\mu(\Lambda) : \rho \int_{U(D)} d\mu(U) U^\dagger \Lambda(U \rho U^{\text{dagger}}) U$$

**Fact 11.** A unitary 2 - design has the property that sampling uniformly from  $\{U_1 \dots U_K\}$  is operationally equivalent to sampling from the Haar measure. Namely  $\mathbb{E}_\mu(\Lambda) = \mathbb{E}_{\text{Harr}}(\Lambda)$ .

**Fact 12.** The uniform distribution over the Clifford group on  $n$  qubits is a unitary 2-design with  $D = 2^n$ .
