

# Quantum LTC With Positive Rate

David Ponnarovsky

September 1, 2022

**preamble.** preamble.

**The Construction.** Fix primes  $q, p_1, p_2, p_3$  such that each of them has 1 residue mode 4. Let  $A_1, A_2, A_3$  be a different generators sets of  $\mathbf{GPL}(2, \mathbb{Z}/q\mathbb{Z})$  obtained by getting the solutions for  $a_0^2 + a_1^2 + a_2^2 + a_3^2 = p_i$  such that each pair  $A_i, A_j$  satisfy the TNC constraint. Then consider the union of the Blance product of

$$\begin{aligned}\Gamma_1 &= \text{Cay}_2(G, A_1) \times_G \text{Cay}_2(G, A_2) \\ \Gamma_2 &= \text{Cay}_2(G, A_1) \times_G \text{Cay}_2(G, A_3) \\ \Gamma_{\square_1} &= (G, \{(g, agb) : a \in A_1, b \in A_2\}) \\ \Gamma_{\square_2} &= (G, \{(g, agc) : a \in A_1, c \in A_3\}) \\ \Gamma_{\square\square} &= (G, \{(gb, agc), (gc, agb) : a \in A_1, b \in A_2, c \in A_3\})\end{aligned}$$

Then define the codes:

$$\begin{aligned}C_z^\perp &= \mathcal{T}(\Gamma_{\square_1}, C_{A_1}^\perp \otimes C_{A_2}^\perp) \\ &\quad | \mathcal{T}(\Gamma_{\square_2}, C_{A_1}^\perp \otimes C_{A_3}^\perp) \\ C_x &= \mathcal{T}(\Gamma_{\square_1}, (C_{A_1} \otimes C_{A_2})^\perp) \\ &\quad | \mathcal{T}(\Gamma_{\square_2}, (C_{A_1} \otimes C_{A_3})^\perp) \\ C_w &= \mathcal{T}(\Gamma_{\square\square}, (C_{A_1} \otimes C_{A_2} \otimes C_{A_3})^\perp)\end{aligned}$$

Notice that the faces of  $\Gamma_{\square_1}, \Gamma_{\square_2}$  are disjointess and here the symbol  $|$  means just joint them together. The main focus here is to prove local testability for computaion base (i.e  $C_x$ ) and for completeness one also must to define the code

$$C_{w_z} = \mathcal{T}(\Gamma_{\square\square}, (C_{A_1}^\perp \otimes C_{A_2}^\perp \otimes C_{A_3}^\perp)^\perp)$$

**What We Currently Have.** Given a canidate for a codeword  $c$  we could check effciently if  $c \in C_z^\perp$ . Additionally summing up the local corretion of each vertex in  $C_x$  yields a codeword in  $C_w$ . Now we would want to show somthing similar to property 1 in Levarier and Zemor which imply that any codeword of  $C_w$  with weigh ben-teeth a linear treashold  $\eta n$  must to be also in  $C_X$ . (And therefore we can reject canidates with heigh weight).

Assume that we have succeeded to do so, Then the testing protocol will be looked as follow, first we check that the canidate is not in  $C_z^\perp$  and then we check that is indeed in  $C_x$ . And repeat again in the phase base. Then

there are constants  $\kappa_1, \kappa_2$

$$\begin{aligned}\text{accept} &\sim \kappa_1 \cdot d(c, C_z^\perp) \\ &\quad + [1 - \kappa_1 \cdot d(c, C_z^\perp)] \kappa_2 d(c, C_x) \\ \text{reject} &\sim [1 - \kappa_1 \cdot d(c, C_z^\perp)] \\ &\quad + \kappa_1 \cdot d(c, C_z^\perp) \cdot [1 - \kappa_2 d(c, C_x)]\end{aligned}$$

**Disclaimer.** The use of the  $\sim$  was made by purpose. The above should be formlyze by inequities. (And this also make another problem as the term  $1 - \kappa_1 \cdot d()$  is in the opposite direaction).

**Claim** for any  $? [[n, k, d]]$  **CSS** code property 1 holds . **Proof.** let  $y \in \{0, 1\}^n$  be a vector such  $y \in G_z^\delta$ , let assume that  $|y|_{C_x^\perp} \leq C_2 d$  then for any  $c \in C_x^\perp$ :

$$\delta r_z \geq |H_z y| = |H_z(y + c)|$$

**Robusstness** Let  $\omega \leq \Delta^2$ . Let  $C_A$  and  $C_B$  be codes of length  $\Delta$  with minimum distance  $d_A$  and  $d_B$ . We shall say that the dual tensor code  $C = C_A \otimes \mathbb{F}_2^B + \mathbb{F}_2^A \otimes C_B$  is  $\omega$ -robust, if for any codeword  $c \in C$  of Hamming weight  $|c| \leq \omega$ , there exist  $A' \subset A, B' \subset B, |A'| \leq |c|/d_B, |B'| \leq |c|/d_A$ , such that  $c_{ab} = 0$  whenever  $a \notin A', b \notin B'$ .

**Definition. Sub-Tensor Pair** We will say that  $C'_A, C'_B$  are sub-tensor pair of  $C_A, C_B$  if each of the code is subspace of  $C_A, C_B$  respectively and in addition one of the minimal codeword in  $C_A$  is also contained in  $C'_A$  (and similar to  $C'_B$ ).

Note that the distance of each subcode is equal to the one from which its driven. And also such code can be generated effciently by choosing  $\Delta$  non trival coordinate of one of the minimal codewords and sets a check nodes over them. (Assunning that  $\Delta$  is even and that there is at least one diffrent codeword in the code wich has an overlap with that minimal codewoed).

**Claim. Subcode Robusstness.** Consider the sub-tensor pair  $C'_A \subset C_A, C'_B \subset C_B$ , such that the dual tensor of  $C_A, C_B$  is  $\omega$ -robust then the dual tensor of  $C'_A, C'_B$  is also  $\omega$ -robust.

**Proof.** Let  $c$  be a codeword in the dual tensor of  $C'_A, C'_B$  then it's clear that  $c$  is also in the dual tensor of  $C_A, C_B$  and therefore there exists  $V, U$  subsets of  $A, B$  respectively such that  $c$  supported only on them,

and their size is less than  $|c|/d_B, |c|/d_A$ . As the length's space of the each of the subcode is identical to his container, and by the fact that the distance of each of the subcode is equal to one which contain it, It's follow that (1)  $U \subset A' = A$  and (2)  $|c|/d_A = |c|/d_{A'}$ .

### Existence Of Sub-Tensor Pair [\[COMMENT\]](#)

[Try to prove existence by the probabilistic method.](#)

**Theorem 1.** *Let  $C_0 = C_A \otimes C_B$ , and  $C_1 = C_A'^{\perp} \otimes C_B'^{perp}$  such that  $C_A', C_B'$  are sub-tensor pair of  $C_A, C_B$ , and each of the code has length  $\Delta$  and relative distance  $\delta$ . Consider the G-blance product of graph with good algebraic expansion  $\Gamma_0^{\square}, \Gamma_1^{\square}$ . Then the pair of the tanner codes  $\mathcal{T}(\Gamma_0^{\square}, C_0)$  and  $\mathcal{T}(\Gamma_1^{\square}, C_1^{\perp})$  define a CSS code with linear distance, positive rate, and local testability for some constant  $\kappa$ .*

**Proof.** First, it's clear that each pair of  $X$  and  $Z$  generators are orthogonal by design. d dd
