## 1 The Construction.

Let  $x_0$  be a codeword of  $C_X/C_Z^\perp$ . Denote by  $w \in \mathbb{F}_2^n$  the binary string presents the  $Z$ -generator that anti commute with the  $X$ -generator corresponds to  $x_0$ . Let  $\mathcal{X} = \{x_0, x_1, \dots, x_{k'}\} \in \mathbb{F}_2^n$  be a subset of a base for the code  $C_X/C_Z^\perp$ . Such  $(\text{span } \mathcal{X}/x_0)|_w$  is Triorthogonal code. Let us denote by  $\mathcal{X}'$  the base  $\{y_1, y_2, \dots, y_{k'}\} \in \mathbb{F}_2^n$  defined such:  $y_i = x_j + x_0$ .

Denote by  $E$  the circuit that encodes the logical  $i$ th bit to  $y_i$ , by  $T^{(w)}$  the application of  $T$  gates on the qubits for which  $w$  act non trivial, means  $T^{(w)}$  is a tensor product of  $T$ 's and identity where on the  $i$ th qubit  $T^{(w)}$  apply  $T$  if  $w_i$  is 1 and identity otherwise. And finally by  $D$  denote the gate that decode binary strings in  $\mathbb{F}_2^n$  back into the logical space.

## 2 Proof of Theorem 1.

**Claim 2.1.** *There exists family of non-trivial distance quantum LDPC codes  $Q$  such the codes span  $\mathcal{X}'$  chosen respect to them has a positive rate. Furthermore, the rate of span  $\mathcal{X}'$  is a asymptotically converges to  $Q$  rate:*

$$|\rho(Q) - \rho(\text{span } \mathcal{X}')| = o(1)$$

*Proof.* Let  $\Delta$  be a constant integer,  $C_0, \tilde{C}_0$  codes over  $\Delta$  bits such  $\tilde{C}_0$  is Triorthogonal and  $C_0$  contains  $\tilde{C}_0$ ,  $C_0$  has parameters  $\Delta[1, \delta_0, \rho_0]$ , and  $C_0^\top$  has relative distance greater than  $\delta_0$ . Let  $C_{\text{Tanner}}$  be a Tanner code, defined by taking an expander graph with good expansion and  $C_0$  as the small code. Let  $C_{\text{initial}}$  be the dual-tensor code obtained by taking  $(C_{\text{Tanner}}^\perp \otimes C_{\text{Tanner}}^\perp)^\perp$ . Notes that first this code has positive rate and  $\Theta(\sqrt{n})$  distance, second this code is an LDPC code as well. Notice also that  $C_{\text{initial}}^\top$  obtained by transporting the parity check matrix, and therefore equals to  $(C_{\text{Tanner}}^{\top, \perp} \otimes C_{\text{Tanner}}^{\top, \perp})^\perp$ . Hence  $C_{\text{initial}}^\top$  has a square root distance as well.

Let  $Q$  the CSS code, obtained by taking the Hyperproduct of  $C_{\text{initial}}$  with itself. So  $Q$  is an quantum qLDPC code with parameters  $[n, \Theta(n^{\frac{1}{4}}), \Theta(n)]$ .  $\square$

**Claim 2.2.** *Let  $|\mathcal{X}'\rangle \propto \sum_{x \in \text{span } \mathcal{X}'} |x\rangle$ . Then  $T^{(w)} |\mathcal{X}'\rangle \propto \sum_{x \in \text{span } i} x$*
