1 The Construction.

Let x_0 be a codeword of $C_X/C_Z^{\perp}$, Denote by $w \in \mathbb{F}_2^n$ the binary string presents the Z-generator that anti commute with the X-generator corresponds to x_0. Let $\mathcal{X} = \{x_0, x_1, ..x_{k'}\} \in \mathbb{F}_2^n$ be a subset of a base for the code $C_X/C_Z^{\perp}$. Such (span $\mathcal{X}/x_0$)$|_w$ is Triorthogonal code. Let us denote by $\mathcal{X}'$ the base $\{y_1, y_2, .., y_{k'}\} \in \mathbb{F}_2^n$ defined such: $y_i = x_j + x_0$.

Denote by E the circuit that encodes the logical ith bit to y_i, by $T^{(w)}$ the application of T gates on the qubits for which w act non trivial, means $T^{(w)}$ is a tensor product of T's and identity where on the ith qubit $T^{(w)}$ apply T if w_i is 1 and identity otherwise. And finally by D denote the gate that decode binary strings in $\mathbb{F}_2^n$ back into the logical space.

2 Proof of Theorem 1.

Claim 2.1. *There exists family of non-trivial distance quantum LDPC codes Q such the codes span $\mathcal{X}'$ chosen respect to them has a positive rate. Furthermore, the rate of span $\mathcal{X}'$ is a asymptotically converges to Q rate:*

$$|\rho(Q) - \rho(\textit{span } \mathcal{X}')| = o(1)$$

Proof. Let Δ be a constant integer, $C_0, \tilde{C}_0$ codes over Δ bits such $\tilde{C}_0$ is Triorthogonal and C_0 contains $\tilde{C}_0$ annd has the parameters $\Delta[1, \delta_0, \rho_0]$. Let C_{Tanner} be a Tanner code, defined by taking an expander graph with good expansion and C_0 as the small code. Let C_{initial} be the dual-tensor code obtained by taking $(C_{\text{Tanner}}^{\perp} \otimes C_{\text{Tanner}}^{\perp})^{\perp}$. Notes that first this code has positive rate and $\Theta(\sqrt{n})$ distance, second this code is an LDPC code as well. that constructed □

Claim 2.2. *Let* $|\mathcal{X}'\rangle \propto \sum_{x \in \textit{span } \mathcal{X}'} |x\rangle$. *Then* $T^{(w)}|\mathcal{X}'\rangle \propto \sum_{x \in \textit{span } i} x$
