$$|{\color{red}0}\rangle$$

Quantum:

$$\frac{1}{\sqrt{2}}\left(|000\rangle {\color{red}-} |111\rangle\right)$$

$$\frac{1}{\sqrt{2}}\left(|0\rangle {\color{red}-} |1\rangle\right)$$

Classical Vs Quantum Encoding.

Classical:

$|011\rangle$

$|0\rangle$

Quantum:

$\frac{1}{\sqrt{2}}(|000\rangle - |111\rangle)$

$\frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$

The C.S Questions.

In the asymptotic regime, can we encode quantum states in codes robust against many errors, as our original massage grows? And in what costs?

Good Classical LDPC Code.

Definition

Let $n \in \mathbb{N}$ and $\rho, \delta \in (0,1)$. We say that C is a **binary linear code** with parameters $[n, \rho n, \delta n]$. If C is a subspace of $\mathbb{F}_2^n$, and the dimension of C is at least ρn and any pair of distinct elements in C differ in at least δn coordinates. We call to the vectors belong to C *codewords*, to ρn the dimension of the code, and to δn the distance of the code.

Good Classical LDPC Code.

Let $n \in \mathbb{N}$ and $\rho, \delta \in (0,1)$. We say that C is a **binary linear code** with parameters $[n, \rho n, \delta n]$. If C is a subspace of $\mathbb{F}_2^n$, and the dimension of C is at least ρn and any pair of distinct elements in C differ in at least δn coordinates. We call to the vectors belong to C *codewords*, to ρn the dimension of the code, and to δn the distance of the code.

Definition

A **family of codes** is an infinite series of codes..

Definition

We will say that a family of codes is a **good code** if its parameters converge into positive values.

Good Classical LDPC Code.

Parity Check Matrix.

Code C is a linear subspace $\Rightarrow$ There is a matrix H such:

$$x \in C \Leftrightarrow Hx = 0$$

We will call H the parity check matrix.

Definition

A codes family will be called LDPC code if weight of any row (col) in H is $O(1)$.

Good Classical LDPC Code.

Example. Repetition code.

Let the Repetition code, $[n, 1, n]$ be the mapping $0 \to 0^n$ and $1 \to 1^n$.

Good Classical LDPC Code.

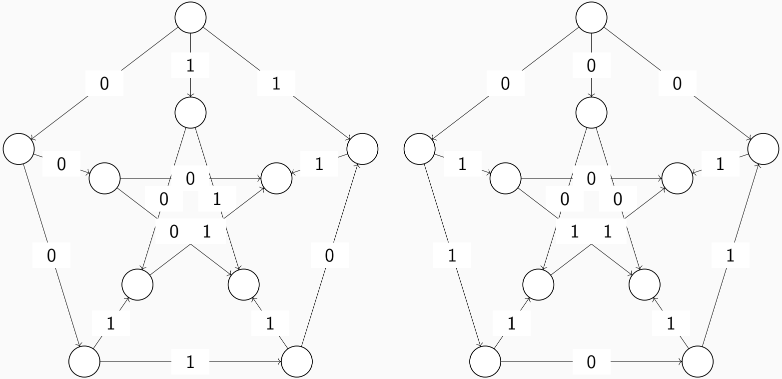
Technic for design LDPC families with positive rate.

Definition

Let Γ be a graph and C_0 be a "small" linear code with finate parameters $[\Delta, \rho\Delta, \delta\Delta]$. Let $C = \mathcal{T}(\Gamma, C_0)$ be all the codewords which, for any vertex $v \in \Gamma$, the local view of v is a codeword of C_0. We say that C is a **Tanner code** of Γ, C_0. Notice that if C_0 is a binary linear code, So C is.

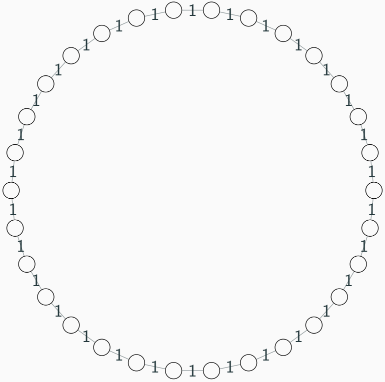
Good Classical LDPC Code.

Example, the parity code on the Peterson graph.

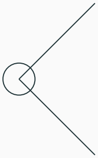


Good Classical LDPC Code.

Another example, the reptiion code can be thought as the tanner graph defind by the parity code on the cyle graph.



$$\overbrace{\begin{bmatrix} 1 & 1 \end{bmatrix}}^{\text{parity check matrix of } C_0}$$



$$\overbrace{\begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}}^{\substack{\text{Parity check matrix of } \mathcal{T}(\Gamma, C_0) \\ \text{Each row associated with vertex check.}}}$$

Good Classical LDPC Code.

Lemma

Tanner codes have a rate of at least $2\rho - 1$.

Good Classical LDPC Code.

Lemma

Tanner codes have a rate of at least $2\rho - 1$.

Proof.

The dimension of the subspace is bounded by the dimension of the container minus the number of restrictions. So assuming non-degeneration of the small code restrictions, we have that any vertex count exactly $(1-\rho)\,\Delta$ restrictions. Hence,

$$\dim C \geq \frac{1}{2}n\Delta - (1-\rho)\,\Delta n = \frac{1}{2}n\Delta\,(2\rho - 1)$$

Clearly, any small code with rate $> \frac{1}{2}$ will yield a code with an asymptotically positive rate $\square$

Good Classical LDPC Code.

Technic for design LDPC families with positive relative distance.

Good Classical LDPC Code.

Technic for design LDPC families with positive relative distance.

Definition

Denote by λ the second eigenvalue of the adjacency matrix of the Δ-regular graph. For our uses, it will be satisfied to define λ-Expander as a graph $G = (V, E)$ such that for any two subsets of vertices $T, S \subset V$, the number of edges between S and T is at most:

$$| E(S, T) - \frac{\Delta}{n}|S||T| | \leq \lambda\sqrt{|S||T|}$$

Good Classical LDPC Code.

Lemma

Using λ-Expander, the Tanner Code defined bit is a good LDPC code.

Good Classical LDPC Code.

Lemma

Using λ-Expander, the Tanner Code defined bit is a good LDPC code.

Proof.

Fix a codeword $x \in C$ and denote By S the support of x over the edges. Namely, a vertex $v \in V$ belongs to S if it connects to nonzero edges regarding the assignment by x, Assume towards contradiction that $|x| = o(n)$. And notice that $|S|$ is at most $2|x|$, Then by The Expander Mixining Lemma we have that:

$$\begin{aligned} \text{bits seen by any } v \in S &\leq \text{ average degree of } v \in G \text{ restricted to} S \\ &= \frac{E(S,S)}{|S|} \leq \frac{\Delta}{n}|S| + \lambda \\ &\leq_{n\to\infty} o(1) + \lambda \end{aligned}$$

$\square$
