# Magic States Distillation Using Quantum LDPC Codes.

#### David Ponarovsky

March 30, 2024

#### 1 Current Status.

- 1. Section 5 Correct. In any CSS code, one can find a large subspace  $\Lambda \subset C_X$  with a dimension that is linear in n and this subspace also satisfies the required relation for distillation. Specifically, for any  $x \in \Lambda$ ,  $y, z \in C_X$ , it holds that xy = 0 and xyz = 0.
- 2. Sections 6 and 7 Incorrect. Initially, I believed that assuming the code is LDPC, one could encode the state  $C_Z^{\perp}$  in constant depth. However, this idea turned out to be incorrect both in calculation and in contrast to the fact that synthesizing the ground state of the Toric code requires  $\Omega(\log n)$  depth.

# 2 Punctured Polyonomial Codes.

For  $\Delta$  prime,  $\Delta < q$ , We have that

$$\sum_{\substack{x \in \mathbb{F}_{\Delta} \\ x \in \Delta}} x^{i+j} =_{\Delta} \sum_{x \in \mathbb{F}_{\Delta}} x^{i+j} =_{\Delta} \begin{cases} 0 & i+j \neq_{q} \Delta - 1 \\ \Delta - 1 & \text{else} \end{cases}$$

So the punctured d-dgree polynomial code is orthogonal for the punctured n-1-d polynomial code. So we can take d=q/2-1, and  $\Delta=\alpha q$  to have  $[\alpha q,q/2-1,q/2-(1-\alpha)q]$  code. For example we can take  $\alpha=7/8$  and have [7/8q,q/2-1,3/8q]. The rate of the code is

$$\sim \frac{1}{2} / \frac{7}{8} = \frac{4}{7} > \frac{1}{2}$$

Claim 2.1. For any  $\Delta > 5$  there are good LDPC family C such that for any  $x, y \in C$  it holds that  $x \cdot y =_{(\Delta - 1)} 0$ .

*Proof.* Consider the Tanner code defined by using the  $\Delta$ -punctured polynomial code as  $C_0$ , where the rate of  $C_0$  is strictly greater than  $\frac{1}{2}$ . Then we have for any  $x,y\in C$ :

$$x \cdot y =_{(\Delta - 1)} \sum_{v \in V^+} x|_v \cdot y|_v =_{(\Delta - 1)} 0$$

## 3 Candidate For Triorthogonal LDPC Code.

Consider the Tannner **Graph**, such that the graph G is bipartite, and every two checks overlap on the ith bucket,  $\Delta$ -size, bits. So for any two checks, we have that

$$\sum_{x=i\cdot\Delta}^{(i+1)\Delta} x^j =_{\Delta} \sum_{x'=(i-1)\cdot\Delta}^{i\Delta} (x'+\Delta)^j$$

$$=_{\Delta} \sum_{x=(i-1)\cdot\Delta}^{i\Delta} x'^{,j} = \sum_{x\in\mathbb{F}_{\Delta}} x^j$$

$$\sum_{x\in\mathbb{F}_{\Delta}} (x+a\Delta)^i (x+b\Delta)^j = \sum_{x\in\mathbb{F}_{\Delta}} x^{i+j}$$

So it's left to show that if take the bipartite graph to be an expander graph then we have a good code.

# 4 Hyprproduct Code of two Triorthogonal Codes.

### 5 Good Codes With Large $\Lambda$ .

**Claim 5.1.** Let  $v_1, v_2..v_k$  vectors in  $\mathbb{F}_2^n$ , then there are  $u_1, u_2..u_{k'}$  for k' > k/2. Such span  $\{u_1, u_2..u_{k'}\} \subset \text{span } \{v_1, v_2..v_k\}$  and for any i, j it holds that  $u_i u_j = 0$ .

```
ı Let J \leftarrow \emptyset
 ı Let J \leftarrow \emptyset
                                                                                   2 for i \in [k/3] do
 i \in [k/2] do
                                                                                            J \leftarrow J \cup \{v_{3i-2}, v_{3i-1}, v_{3i}\}
         J \leftarrow J \cup \{v_{2i-1}, v_{2i}\}
                                                                                            for S \subset J do
         for S \subset J do
                                                                                                  Compute the vector m_S

 6
                                                                                                 m_{S,j,j'} = u_{j'}u_j \sum_{w \in S} w
         Pick S such m_S = 0 and set
                                                                                            Pick S such m_S = 0 and set
         \begin{array}{l} u_i \leftarrow \sum_{w \in S} w \\ \text{Choose randomly } w \in S \text{ and set} \end{array}
                                                                                            u_i \leftarrow \sum_{w \in S} w
Choose randomly w \in S and set
           J \leftarrow J/w
10 end
                                                                                  10 end
   : Find commuted vectors u_1, u_2, ... u_{k'}
                                                                                      : Find commuted vectors u_1, u_2, ... u_{k'}
```

*Proof.* Consider Algorithm 1a, We are going to prove that at line number (8) the alg always finds a subset S that satisfies the equality. Assume not. On one hand, the number of possible values that  $m_S$  can have is  $2^i - 1$ . On the other hand, since J contains i + 1 vectors on the ith iteration, it follows that the number of subsets is  $2^{i+1} - 1 \ge 2^i$ .

Therefore, there must be at least two different subsets S and S' such that  $u_S = u_{S'}$ . However, this means that

$$m_{S\Delta S',j} = u_j \sum_{w \in S\Delta S'} w = u_j \left( \sum_{w \in S\Delta S'} w + 2 \sum_{w \in S\cap S'} w \right)$$
$$= m_{S,j} + m_{S',j} = 0$$

Thus,  $m_{S\Delta S'}=0$ . Additionally, it is clear that the rank does not decrease, as for  $u_i$ , there exists one  $v_j$  such that only  $u_i$  is supported by  $v_j$ .

Claim 5.2. Let  $v_1, v_2..v_k$  vectors in  $\mathbb{F}_2^n$  and m be an integer m < k, then there are  $u_1, u_2..u_{k'}$  for k' > k/2-m. Such span  $\{u_1, u_2..u_{k'}\} \subset \text{span } \{v_{m+1}, v_{m+2}..v_k\}$ , for any i, j it holds that  $u_iu_j = 0$  and for any  $i \in ]k'$ ,  $j \leq m$  it holds that  $u_iv_j = 0$ .

*Proof.* Modify the Algorithm 1a as follows, Initialize  $u_1, u_m$  to be  $v_1, ..., v_m$  and  $J = \{v_{m+1}, ..., v_{2m+2}\}$ . Notice that in the *i*th iteration, for the counting argument to works in the proof of Claim 5.1, we have to ensure that:

$$|J| \ge m+i+1, \text{ So } m+i+1 \le k-m-i$$
 
$$\Rightarrow i \le k/2-m-\frac{1}{2}$$

In the end,  $u_{m+1}, u_{m+2}, ..., u_{k'}$  will satisfy the equations.

**Claim 5.3.** Let  $v_1, v_2..v_k$  vectors in  $\mathbb{F}_2^n$ , then there are  $u_1, u_2..u_{k'}$  for k' > k/4. Such span  $\{u_1, u_2..u_{k'}\} \subset span \{v_1, v_2..v_k\}$ . And for any  $i, j \sum u_{i,k}u_{j,k} =_4 0$ .

П

*Proof.* Use the Algorithm 1a twice. However, in the second iteration, define  $m_{S,j}$  to be the product of module 4. Note that  $m_{S,j}$  must be either 4n or 4n+2. Thus, we can follow the proof of Claim 5.1.

**Claim 5.4.** [COMMENT] Complete for the above the version, which handle triples. number of options is  $(2^i)^2 = 2^{2i}$  and therefore we have the correctness if |J| > 2i + 1.

**Claim 5.5.** Consider the Left-Right  $(\Delta,n)$ -Complex  $\Gamma$ . dim  $C_X/C_Z^{\perp} \cap C_Z/C_X^{\perp}$  is linear in n.

*Proof.* The rates of both  $C_X/C_Z^{\perp}$  and  $C_Z^{\perp}/C_X^{\perp}$  are  $(2\rho-1)^2$ , where  $\rho$  can be any number in the range (0,1) [LZ22]. Consider choosing  $\rho$  such that the rates of the quotient spaces are strictly greater than  $\frac{1}{2} + \alpha$ . This implies that the rate of their intersection is greater than  $2\alpha$ .

**Corollary 5.1.** Fix the rate of the small codes  $C_A$  and  $C_B$  to  $\rho = \frac{1}{2} + \alpha$ . There is a subspace  $\Lambda \subset C_X/C_Z^{\perp}$  at rate  $\frac{1}{4} \cdot 2\alpha$  such that for any  $x \in \Lambda$  and  $y, z \in C_Z^{\perp} \cup \Lambda$  it holds that:

1. 
$$xy =_4 0$$

2. 
$$xyz =_4 \sum_i x_i y_i z_i =_4 0$$

**Claim 5.6.** Consider  $C, \Lambda$  and  $C', \Lambda'$  defined in ??. Denote by  $\bar{\Lambda}$  the subspace  $C/\Lambda$ . Then:

$$d(C'/\bar{\Lambda}') \ge d(C/\bar{\Lambda})$$

*Proof.* The way we perform Guess elimination is critical. We want to make sure that we do not add an  $\Lambda$  row to a  $\bar{\Lambda}$  row. [COMMENT] Continue, Easy. Just need to perform the row reduction when rows of  $\Lambda$  at bottom, and then rotate the matrix  $\curvearrowright$ 

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} \curvearrowright \begin{bmatrix} D & C \\ B & A \end{bmatrix}$$

**Claim 5.7** (Not Formal). It is easy to see that by using concatenation again, one can obtain the code dim  $\Lambda' \leftarrow \frac{1}{2} \dim \Lambda'$ . For any  $x \in \text{gen } \Lambda'$ ,  $|x|_4 = 1$ , and for any  $x \in C'/\Lambda'$ , we have  $|x|_4 = 0$ .

**Proof.** [COMMENT] We will do it by iterating the generators of C after performing rows reduction to the generator matrix. Now we will concatenate the i coordinate to complete the weight of the ith row to satisfy the requirements.

# 6 Compute $|C_Z^{\perp}\rangle$ In Constant Depth. [COMMENT] Wrong Section.

Let  $C_0$  be a  $\Delta$ -length error linear binary code,  $\Gamma$  a  $\Delta$ -regular bipartite graph, and let  $C_Z$  be the Tanner code defined by  $C_0$  and  $\Gamma$ . We are about to prove that the uniform superposition over  $C_Z^\perp$  codewords can be computed with constant probability at a depth dependent only on  $\Delta$ , in particular independent of the  $C_Z^\perp$ -length. For this, we are going to use Proposition 10 in [MN98], which states that both the encoder and the decoder of any stabilizer m-length code can be implemented by a circuit at depth  $\Theta(\log m)$  with  $\Theta(m^2)$  ancillae.

Claim 6.1. Let G be a  $\Delta$ -regular bipartite graph, and denote by  $C_Z^{\perp}$  the dual-tanner code  $\mathcal{T}(G, C_0^{\perp})^{\perp}$ . Then there is a circuit that with constant probability computes the state  $|C_Z^{\perp}\rangle$  at  $\Theta(\log \Delta)$  depth, and  $\Theta(\Delta^2)n$  ancillary qubits.

*Proof.* Let  $E_v$  and  $D_v$  be the encoder and the decoder of  $C_0$  over the local view of vertex v, By [MN98] we have that both have depth  $\Theta(\log \Delta)$  and require  $\Delta^2$  ancillae. Since  $\Gamma$  is bipartite, we can decompose V into  $V^-$  and  $V^+$  such that the local views of any two vertices in  $V^\pm$  are disjoint. Therefore, for any two different vertices  $v, u \in V^\pm$ , the encoders  $E_v$  and  $E_u$  act on disjoint subsets of qubits, each corresponding to the local view of either v or v. Consider the following algorithm:

- 1 Initialize 2n qubits.
- <sup>2</sup> Call the left and right segments L and R.
- з Apply  $E_v$  in parallel on L for any  $v \in V^+$ .
- 4 Apply  $E_v$  in parallel on R for any  $v \in V^-$ .
- 5 XOR R into L by applying CNOT from the ith bit of R to the ith bit of L.
- 6 Apply  $D_v$  in parallel on R for any  $v \in V^-$ .
- <sup>7</sup> Apply  $H^k$  on L. And measure.
- 8 Accept if the result in  $C_Z$

**Algorithm 1:** Compute  $|C_Z^{\perp}\rangle$ 

For any  $v \in V$ , let  $|z_v\rangle$  be the superposition of codewords in  $C_0$  supported by the local view of v. Similarly, for any subset of vertices  $W \subset V$ , let  $|z_W\rangle$  be the uniform superposition over the subspace spanned by the generators supported by the vertices in W. In other words:

$$|z_W\rangle = |\sum_{v \in W} z_v\rangle$$

Using the notation, applying the encoders  $E_v$ ,  $E_u$  for any pair of vertices with disjoints local view become:

$$E_v \cup E_u |0\rangle^n = E_v |0 + z_u\rangle = E_v |0_{/u\text{'s view}}\rangle \otimes |z_u\rangle$$
$$= |z_v\rangle |z_u\rangle = |z_u + z_v\rangle = |z_{\{u,v\}}\rangle$$

So applying all the encoders  $E_v$  at once over the positive vertices results in:

$$(\bigcup_{v \in V^{+}} E_{v}) |0\rangle^{n} = (\bigcup_{v \in V^{+}/v_{0}} E_{v}) |z_{v_{0}} + 0\rangle = |z_{V^{+}}\rangle$$

Thus the whole computation sum up into:

$$(\cup_{v \in V^{+}} E_{v}) \otimes (\cup_{v \in V^{+}} E_{v}) \qquad |0\rangle^{n} \otimes |0\rangle^{n} \mapsto$$

$$CNOT \sum_{z \in A} \sum_{z' \in B} \qquad |z + z'\rangle |z'\rangle \mapsto$$

$$\sum_{z \in A} \sum_{z' \in B} \qquad |z + z'\rangle (-1)^{wz'} |w\rangle \mapsto$$

So if  $w \in C_Z$  then clearly z'w = 0. The probability for that to occur is

$$\Pr[w \in C_Z] = \frac{|C_Z|}{\mathbb{F}_2^n} = 2^{(\rho-1)n}$$

7 Distillate  $|\Lambda + C_Z^\perp 
angle$  Into Magic.

Let  $|f\rangle$  be a codeword in  $C_X$ , and let  $\hat{X}_g$  be the indicator that equals 1 if f has support on generator g, and 0 otherwise. Observe that applying  $T^{\otimes}$  on  $|f\rangle$  yields the state:

$$\begin{split} T^{\otimes n} \left| f \right\rangle &= T^{\otimes n} \left| \sum_{g} \hat{X}_g g \right\rangle = \exp \left( i \pi / 4 \sum_{g} \hat{X}_g |g| - 2 \cdot i \pi / 4 \sum_{g,h} \hat{X}_g \hat{X}_h |g \cdot h| \right. \\ &+ 4 \cdot i \pi / 4 \sum_{g,h} \hat{X}_g \hat{X}_h \hat{X}_l |g \cdot h \cdot l| - 8 \cdot i \pi / 4 \cdot \text{ integers } \right) |f\rangle \\ &= \exp \left( i \pi / 4 \sum_{g} \hat{X}_g |g| - 2 \cdot \pi / 4 \sum_{g,h} \hat{X}_g \hat{X}_h |g \cdot h| + 4 \cdot i \pi / 4 \sum_{g,h} \hat{X}_g \hat{X}_h \hat{X}_l |g \cdot h \cdot l| \right) |f\rangle \end{split}$$

So in our case:

$$\begin{split} T^{\otimes n} \left| f \right\rangle &= \\ &= \exp \left( i \pi / 4 \sum_{g \in \, \text{gen } \Lambda} \hat{X}_g \right. \\ &\left. - 2 \cdot \pi / 4 \sum_{g,h \in \, \text{gen } C_Z^\perp} \hat{X}_g \hat{X}_h |g \cdot h| \right. \\ &\left. + 4 \cdot i \pi / 4 \sum_{g,h \in \, \text{gen } C_Z^\perp} \hat{X}_g \hat{X}_h \hat{X}_l |g \cdot h \cdot l| \right) |f\rangle \end{split}$$

So eventually, we have a product of gates when non-Clifford gates are applied on only on generators of  $C_Z^{\perp}$ .

$$T^n \left| f \right\rangle = \prod_{g \in \, \text{gen } \Lambda} T_g \quad \prod_{g,h \in \, \text{gen } C_Z^\perp} \{CS_{g,h} | CZ_{g,h} | I\} \quad \prod_{g,h,l \in \, \text{gen } C_Z^\perp} \{CCZ_{g,h,l} | I\} \left| f \right\rangle$$

Decompose  $f = f_1 + f_2$ , where  $f_1$  is supported only on  $C_X/C_Z^{\perp}$  and  $f_2$  is supported only on  $C_Z^{\perp}$ . By using commuting relations, the above can be turned into.

$$\begin{split} T^n \left| f \right\rangle &= \prod_{g \in \, \text{gen} \, \Lambda} T_g \ X_{f_1} \\ & \prod_{g,h \in \, \text{gen} \, C_Z^\perp} \{ CS_{g,h} | CZ_{g,h} | I \} \ \prod_{g,h,l \in \, \text{gen} \, C_Z^\perp} \{ CCZ_{g,h,l} | I \} \left| f_2 \right\rangle \end{split}$$

Denote by  $M_1, M_2$  the gates:

$$\begin{split} M_1 &= \prod_{g \in \text{ gen } \Lambda, h} \{CZ_{g,h}|I\} \\ M_2 &= \prod_{g,h \in \text{ gen } C_Z^\perp} \{CS_{g,h}|CZ_{g,h}|I\} \quad \prod_{g,h,l \in \text{ gen } C_Z^\perp} \{CCZ_{g,h,l}|I\} \end{split}$$

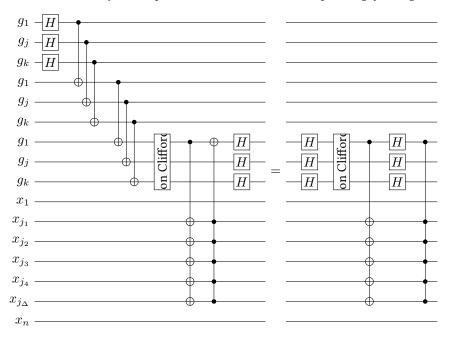

And then we get that

$$\begin{split} \prod_{g \in \, \text{gen } \Lambda} T_g \, |f\rangle &= M_1^\dagger T^n M_2^\dagger \, |f\rangle \\ \prod_{g \in \, \text{gen } \Lambda} T_g \, |f\rangle &= M_1^\dagger T^n \; \; E \; \; L[M_2^\dagger] \; \; |L[f]\rangle \end{split}$$

Claim 7.1. Let  $v \in V^-$ , and let  $g_1$  be the generator supported by v, which matches an assignment of a codeword in  $C_A \otimes C_B$  on the local view of v. Denote by  $U_{v,g_1}$  the control-gate which, depending on the control bit (v,1), turns on  $g_1$  over the edges associated with the local view of v in the graph G. Then, the depth of  $U_{v,g_1}$  depend only on  $\Delta$ .

**Claim 7.2.** Let  $(v, g_1)$  and  $(u, g_2)$  be control wires for two different generators in the graph G. Then  $U_{v,g_1}$  and  $U_{u,g_2}$  [COMMENT] There must be a claim about the relationship between two different generators intersection, But I don't sure exactly why.

**Definition 7.1.** We say that a quantum circuit C is well error spreading if the light cone define by any T.

#### Claim 7.3. The state:

$$\begin{split} \sum_{z \in C_Z^\perp} \exp \Big( - 2 \cdot \pi/4 \sum_{g,h \in \text{ gen } C_Z^\perp} \hat{X}_g \hat{X}_h |g \cdot h| \\ + 4 \cdot i \pi/4 \sum_{g,h \in \text{ gen } C_Z^\perp} \hat{X}_g \hat{X}_h \hat{X}_l |g \cdot h \cdot l| \Big) \, |z\rangle \end{split}$$

Can be computed such that any

*Proof.* Denote by  $U_v$  the gate which turn on all the generators supported on v. As any of them is just of a code word of  $C_A \otimes C_B$ , namely turning on generator require touching at most constant number of qubits combing

**Claim 7.4.** The state  $\left(M_2^{\dagger} \otimes I\right) |C_Z^{\perp} + \Lambda\rangle |0\rangle$  can be computed, such that the light cone depth of any non-clifford gate is bounded by constant.

Proof.

$$(I \otimes H_X) CX_{n \to n} (E \otimes E) \quad I \otimes L[M_2^{\dagger}] \prod_{\substack{J \in \{ \text{gen } \Lambda, g \in J \\ \text{gen } C_Z^{\dagger} \} \}}} \prod_{j \in \{ \text{gen } \Lambda, g \in J \}} (I + X_{L[g]}) \qquad |0\rangle |0\rangle$$

$$= (I \otimes H_X) CX_{n \to n} \sum_{\substack{z \in C_Z^{\dagger} \\ x \in \Lambda}} e^{\varphi(z)} \qquad |x\rangle |z\rangle$$

$$= \sum_{\substack{z \in C_Z^{\dagger} \\ x \in \Lambda}} e^{\varphi(z)} \qquad |x + z\rangle |0\rangle$$

$$= \sum_{\substack{z \in C_Z^{\dagger} \\ x \in \Lambda}} (M_2^{\dagger} \otimes I) \qquad |x + z\rangle |0\rangle$$

$$= (M_2^{\dagger} \otimes I) \qquad |C_Z^{\dagger} + \Lambda\rangle |0\rangle$$

Denote by  $p \in [0, 1]$  the error rate of input magic states, and let  $|A\rangle$  be an ancilla initialized to a one-qubit magic state. This  $|A\rangle$  can be used to compute the T gate, with a probability of Z error occurring with a probability of p [BH12].

**Claim 7.5.** There are constant numbers  $\zeta_{\Delta}, \xi_{\Delta}$ , and a circuit C such that:

1. In the no-noise setting, The circuit compute the state

$$\mathcal{C} |0\rangle^{\Theta(n)} \otimes |A\rangle^{\Theta(n)} \to \prod_{g \in \text{gen } \Lambda} T_g |C_Z^{\perp} + \Lambda\rangle$$

2. Otherwise, the circuit computes the state

$$\mathcal{C} \left| 0 \right\rangle^{\Theta(n)} \otimes \left| A \right\rangle^{\Theta(n)} \to Z^e \quad \prod_{g \in \, \mathrm{gen} \, \Lambda} T_g \left| C_Z^\perp + \Lambda \right\rangle$$

, where the probability that  $e_i = 1$  is less than  $\zeta_{\Delta} \cdot p$ . Additionally, for any i, there are at most  $\xi_{\Delta}$  indices j such that  $e_i$  and  $e_j$  are dependent.

*Proof.* Concatinate the  $T^n \otimes I$  with the gate in Claim 7.4.

**Claim 7.6.** For any  $\alpha \in (0,1)$  the probability that  $|e| > (1+\alpha)p\zeta_{\Delta}$  is less than:

$$\mathbf{Pr}\left[|e| > (1+\alpha)\mathbf{E}\left[|e|\right]\right] < \frac{1 \cdot \xi_{\Delta} n}{\alpha^2 \zeta_{\Delta}^2 p^2 n^2} = o\left(1/n\right)$$

*Proof.* By the Chebyshev inequality, notice that the number for which  $\mathbf{E}\left[e_{i}e_{j}\right] - \mathbf{E}\left[e_{i}\right]\mathbf{E}\left[e_{j}\right] \neq 0$  is less than  $\xi_{\Delta}n$ .

**Definition 7.2.** We will said that a decoder  $\mathcal{D}$  for the good qunatum LDPC code is an good-local decoder if

- 1. There is a treashold  $\mu n$  such that if the error size is less than  $|e| < \mu n$  then  $\mathcal{D}$  correct e in constant number of rounds. With probability 1 o(1/n).
- 2. In any rounds  $\mathcal{D}$  performs at most O(n) work (depth  $\times$  width).
- 3. The above is true in operation-noisy settings, where there is a probability of p for an error to occur after acting on a qubit.  $(\star)$

 $\star$  The motivation for this is that if the decoder does not act on the qubit, then it also does not apply a T gate on it. Therefore, in the distillation setting, there is zero chance for an error to occur.

Claim 7.7. Suppose there is a good local decoder  $\mathcal{D}$  for the good qLDPC code. Then, there exists  $p_0$  such that for any sufficiently large n, there is a distillation protocol that, given  $\Theta(n)$  magic states at an error rate  $p < p_0$ , successfully distills  $\Theta(n)$  perfect magic states with a probability of 1 - o(1/n). Furthermore, the protocol's space and time complexity (both quantum and classical) are  $\Theta(n)$  and  $\Theta(n^2)$ , respectively.
