Exsitance of family of statmensts and quantum proofs, such that any slightly noisy version of the proofs is still a proof and cann't be yilded by

'weak' computations.

from good qLDPC codes [ABN22]

Introduction.

The work assumes only a basic knowledge of linear algebra and combinatorics. So we believe that every computer science graduate will be able to enjoy reading it, understand the subject very well, and use it as a gateway for starting research in the field.

Bob is willing to send some message to Alice through

Bob is willing to send some message to Alice through a noisy chanell in which bits might be fliped.

Bob is willing to send some message to Alice through a noisy chanell in which bits might be fliped. By sending extra bits, i.e duplicate any bit tree times, B can ensure that A could still decode the original message in the presence of a single bit-flip.

Non formally, We call for the embedding of entitis in a larger space a code. And the questions that we would like to ask are:

• Can we come up with a code that tolerates * bits flip?

Non formally, We call for the embedding of entitis in a larger space a code. And the questions that we would like to ask are:

- Can we come up with a code that tolerates * bits flip?
- At the cost of at most * extra bits?

Non formally, We call for the embedding of entitis in a larger space a code. And the questions that we would like to ask are:

- Can we come up with a code that tolerates * bits flip?
- At the cost of at most * extra bits?
- Can we ensure an efficient decoding (and checking) sechme?

Non formally, We call for the embedding of entitis in a larger space a code. And the questions that we would like to ask are:

- Can we come up with a code that tolerates * bits flip?
- At the cost of at most * extra bits?
- Can we ensure an efficient decoding (and checking) sechme?
- In the assymptotic regime, when the size of the original message grows.

Definition

Let $n \in \mathbb{N}$ and $\rho, \delta \in (0,1)$. We say that C is a **binary linear code** with parameters $[n, \rho n, \delta n]$. If C is a subspace of \mathbb{F}_2^n , and the dimension of C is at least ρn . In addition, we call the vectors belong to C codewords and define the distance of C to be the minimal number of different bits between any codewords pair of C.

Definition

A **family of codes** is an infinite series of codes. Additionally, suppose the rates and relative distances converge into constant values ρ, δ . In that case, we abuse the notation and call that family of codes a code with $[n, \rho n, \delta n]$ for fixed $\rho, \delta \in [0, 1)$, and infinite integers $n \in \mathbb{N}$.

Definition

We will say that a family of codes is a **good code** if its parameters converge into positive values.

Tanner Codes.

Definition

Let Γ be a graph and C_0 be a "small" linear code with finate parameters $[\Delta, \rho \Delta, \delta \Delta]$. Let $C = \mathcal{T}(\Gamma, C_0)$ be all the codewords which, for any vertex $v \in \Gamma$, the local view of v is a codeword of C_0 . We say that C is a **Tanner code** of Γ , C_0 . Notice that if C_0 is a binary linear code, So C is.

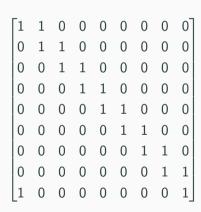

Tanner Codes.

Example, the parity code on the Peterson graph.

Another example, the repttion code can be thought as the tanner graph defind by the parity code on the cyle graph.

Another example, the repttion code can be thought as the tanner graph defind by the parity code on the cyle graph.

Back to the quantum noise.

Quantum Noise.

Quantum Noise.

Quantum Noise.

$$\begin{array}{l} |{\color{red}0}10101\rangle + |{\color{red}1}10100\rangle - |{\color{red}1}111110\rangle \\ |{\color{red}1}10101\rangle + |{\color{red}0}10100\rangle + |{\color{red}0}11110\rangle \end{array}$$

Definition (CSS Code)

Let C_X , C_Z classical linear codes such that $C_Z^{\perp} \subset C_X$ define the $Q(C_X, C_Z)$ to be all the codewords with following structure:

$$|\mathbf{x}\rangle := |x + C_Z^{\perp}\rangle = \frac{1}{\sqrt{C_Z^{\perp}}} \sum_{z \in C_Z^{\perp}} |x + z\rangle$$

Definition (*w*-Robustness)

Let C_A and C_B be codes of length Δ with minimum distance $\delta_0\Delta$. $C = \left(C_A^\perp \otimes C_B^\perp\right)^\perp$ will be said to be w-robust if for any codeword $c \in C$ of weight less than w, it follows that c can be decomposed into a sum of c = t + s such that $t \in C_A \otimes \mathbb{F}^B$ and $s \in \mathbb{F}^A \otimes C_B$, where s and t are each supported on at most $\frac{w}{\delta_0\Delta}$ rows and columns. For convenience, we will denote by B' (A') the rows (columns) supporting t (s) and use the notation $t \in C_A \otimes \mathbb{F}^{B'}$.

Definition (*p*-Resistance to Puncturing.)

Let p, w be integers. We will say that the dual tensor code $C_A \otimes \mathbb{F} + \mathbb{F} \otimes C_B$ is w-robust with p-resistance to puncturing, if the code obtained by removing (puncturing) a subset of at most p rows and columns is w-robust.

Definition (Quantum Tanner Code.)

Let Γ be a group at size n. And let A,B be a two generator set of Γ such that if $a \in A$ (B) then also $a^{-1} \in A$ (B^{-1}) and that for any $g \in \Gamma$, $a \in A$, $b \in B$ it holds that $g \neq agb$. Define the left-right Cayley complex to be the graph $G = (\Gamma, E)$ obtained by taking the union of the two Cayley graphs generated by A and B. So the vertices pair u, v are set on a square diagonal only if there are $a \in A$ and $b \in B$ such that u = avb. We can assume that G is a bipartite graph (otherwise just take $\Gamma' = \Gamma \times \mathbb{Z}_2$ and define the product to be $a(u, \pm) = (au, \mp)$).

Definition (Quantum Tanner Code.)

Now divide the graph into positive and negative vertices according to their coloring V_- and V_+ . And define the positive graph to be $G^+ = (V_+, E)$ and by $G^- = (V_-, E)$ the negative graph, where E denotes the squares, put differently there is an edge between v and u in G^+ if both vertices are positive and they are laid on the ends of a square's diagonal.

The quantum Tanner code is a CSS code, such that C_X is defined to be the classical Tanner code $\mathcal{T}\left(G^+,\left(C_A^\perp\otimes C_B^\perp\right)^\perp\right)$ and C_Z is defined as $\mathcal{T}\left(G^-,\left(C_A\otimes C_B^\perp\right)^\perp\right)$. Note that in contrast to the classical Tanner code, in the quantum case it will be more convenient to think of codewords as assignments set on the squares and not on the edges.
