## **1** Good Codes With Large $\Lambda$ .

**Definition 1.1.** Let  $M \in \mathbb{F}_2^{k \times n}$  upper triangular matrix such that k < n. We say that M has the 1-stairs property if  $M_{ij} = 1$  any j < i.

**Claim 1.1.** Any  $M \in \mathbb{F}_2^{k \times n}$  upper triangular matrix can be turn into upper triangular matrix that has the 1-stairs property by elementary operation.

| [1  | 1 | 1 | 1 | 1 | • | • | • |   |
|---|---|---|---|---|---|---|---|---|
| 0   | 1 | 1 | 1 | 1 |   |   |   |   |
| 0   | 0 | 1 | 1 | 1 |   |   |   |   |
| 0   | 0 | 0 | 1 | 1 |   |   |   |   |
| $\begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$ | 0 | 0 | 0 | 1 |   |   |   | ٠ |

*Proof.* Consider the following algorithm: Let M be our initial matrix. We iterate over the rows from left to right. In the ith iteration, we check for any row j < i if  $M_{ji} = 1$ . If not, we set M to be the matrix obtained by adding the ith row to the jth row. Since M is an upper triangular matrix, adding the ith row does not change any entry  $M_{js}$  for s < i. Therefore, the obtained matrix is still an upper triangular matrix and the entries at  $M_{is}$  for j, s < i remain the same, namely 1 if and only if  $j \le s$ .

Continuing with the process eventually yields, after k iterations, a matrix with the 1-stair property.  $\Box$ 

**Claim 1.2.** Let C be a [n,k,d] binary linear code, and let  $\Lambda$  be subcode  $\Lambda \subset C$  at dimension k'. Then there exists a code  $C' = [\leq 2n, \geq k - k'/2, d]$  and a subcode of it  $\Lambda'$  in it at dimension  $\geq k'/2$ , such every triple  $x \in \Lambda'$  and  $y, z \in C'$  we have

1. 
$$x \cdot y = 0$$

$$2. \ x \cdot y \cdot z = 0$$

*Proof.* First, consider the upper triangular matrix obtained by applying Gaussian elimination on  $\Lambda$  that has the 1-stair property. Now, consider the following process: go uphill, from right to left, iterating over the matrix. Let j=k be the first non-zero coordinate in the bottom row of the matrix. In the ith iteration, we ask how many rows  $u_m$ , such that m < j, satisfy  $u_m u_j = 0$ .

- If more than half of such  $u_m$  satisfy the equality, then we move on to the next iteration.
- Otherwise, we encode the jth coordinate by  $C_0$ , which maps  $1 \to w$  such that  $w \cdot w = 0$ . This flips the value of  $u_m u_j$  for any pair, so we get that the majority of pairs satisfy the equality.

Notice that because we iterate on the upper triangular matrix, we don't change the value of  $u_m u_{j'}$  for any j' > j (since its jth coordinate was 0 before the encoding, the encoded bit will also be 0, thus not affecting the multiplication).

Denote the set of the obtained vectors by  $\Gamma$ . Let  $S \subset \Gamma$  be the group of vectors for which there exists at least one vector in  $\Gamma$  whose multiplication with them is not zero. Note that the total number of pairs with zero multiplication is greater than:

$$\frac{k'-1}{2} + \frac{k'-2}{2} + \ldots + \frac{2}{2} = \frac{1}{2} \frac{(k'-1)(k'-2)}{2}$$

So

$$|S| \cdot (k'-1) \le {k' \choose 2} - \frac{1}{2} \frac{(k'-1)(k'-2)}{2} < \frac{k'(k'-1)}{2} \Rightarrow |S| < \frac{k'}{2}$$

Set  $\Lambda' \leftarrow \Gamma/S$ . And we got what we wanted.

Claim 1.3. We can repeat Claim 1.2 by considering triple multiplications instead of pair multiplications. Let  $C_2$  and  $C_3$  be the codes obtained from this process. We can then guarantee the existence of  $\Lambda_2 \in C_2$  and  $\Lambda_3 \in C_3$  such that for any  $x, y \in \Lambda_2$ , xy = 0, and for any triple  $x, y, z \in \Lambda_3$ , xyz = 0. The code  $C_2 \otimes C_3$  has a group of codewords  $\Lambda_{23}$  such that for any  $x, y, z \in \Lambda_{23}$ , xy = 0 and xyz = 0.

**Claim 1.4.** Suppose that a set of vectors  $\Lambda \subset C$  satisfies the relation xy=0 and xyz=0 for any  $x,y,z\in \Lambda$ . Then, there exists a code C' with a code length roughly equal to C and a subset  $\Lambda' \subset C'$  such that for any distinct  $x,y,z\in \Lambda'$ , xy=0, xyz=0, and xx=4 1.

*Proof.* We return to the process in Claim 1.2, but taking the standard upper triangular form of  $\Lambda$  instead the 1-stairs form. Notice that the rows are linear combinations of the original vectors in  $\Lambda$  and therefore also preserve the original relations. So now, for any j < k, we have that encoding the  $M_{jj}$  bit only affects the multiplication of  $u_j u_j$ . Thus, we will encode the jth coordinate such that the multiplication of a row by itself is 1 residue 4.

**Claim 1.5.** We can repeat Claim 1.2 by flipping the bit, ensuring that the majority of pairs and triple multiplications are zero. In the end, we will have the following inequality:

$$|S| \cdot (k + k^2) \le \frac{1}{2} (k^2 + k^3)$$

And still we will get that  $|S| \le k/2$
